
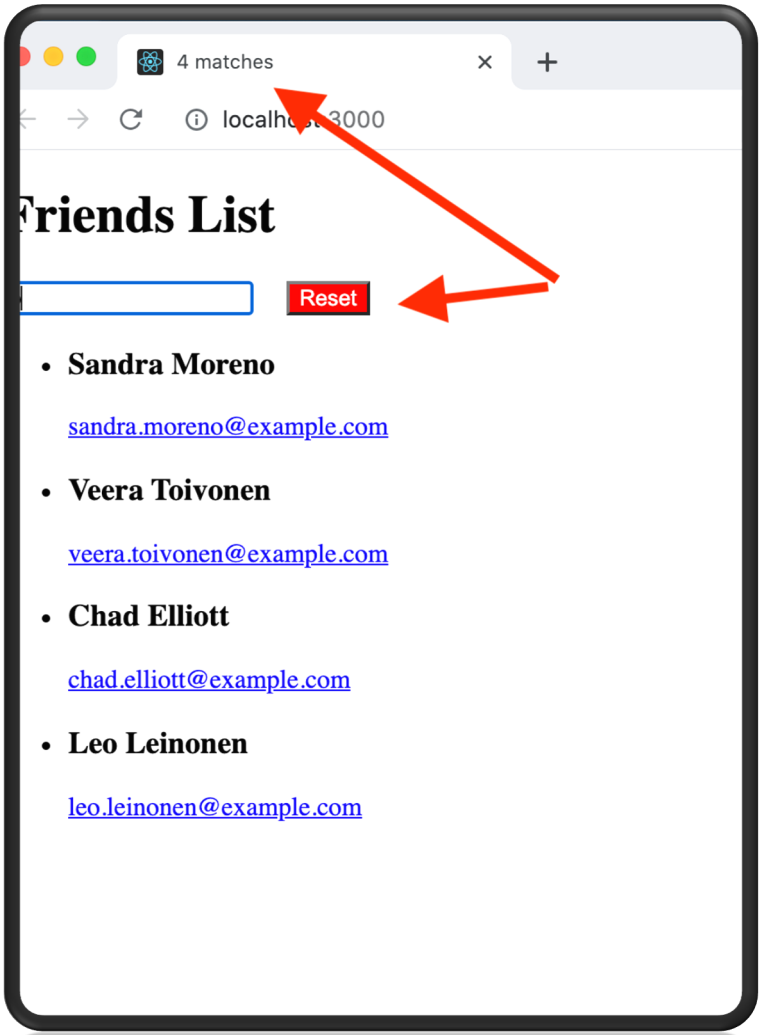
ReactJS.

The Component model (Contd)

Topics

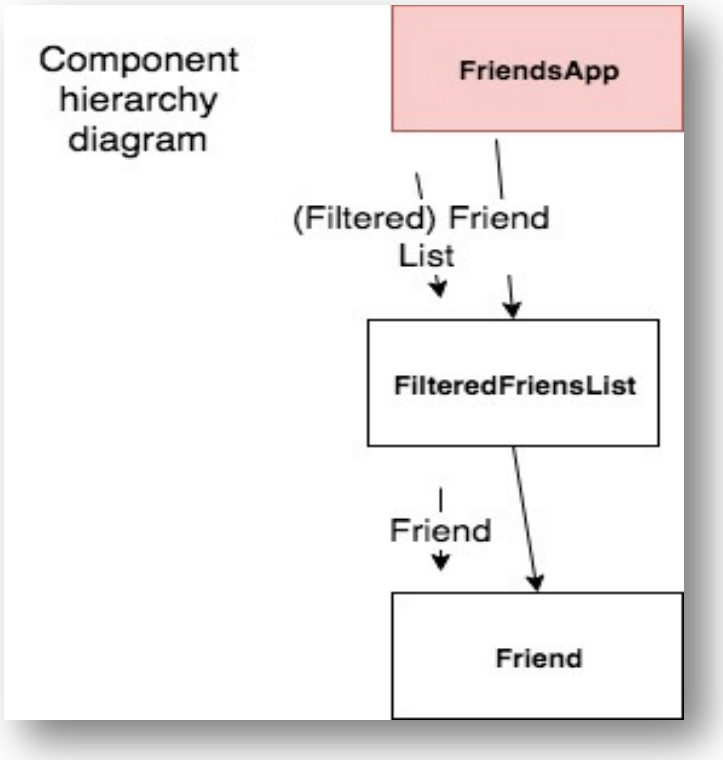
- **Hooks and Component Lifecycle.**
- **Data Flow patterns – Data Down, Action Up pattern.**
- **The Virtual DOM**

Sample App 1 – Version 2



- **App UI changes:**
  1. **A 'Reset' button – loads a new list of friends. Overwriting the current list.**
  2. **Browser tab title - shows # of matching friends (side effect).**
- **See lecture archive for source code**

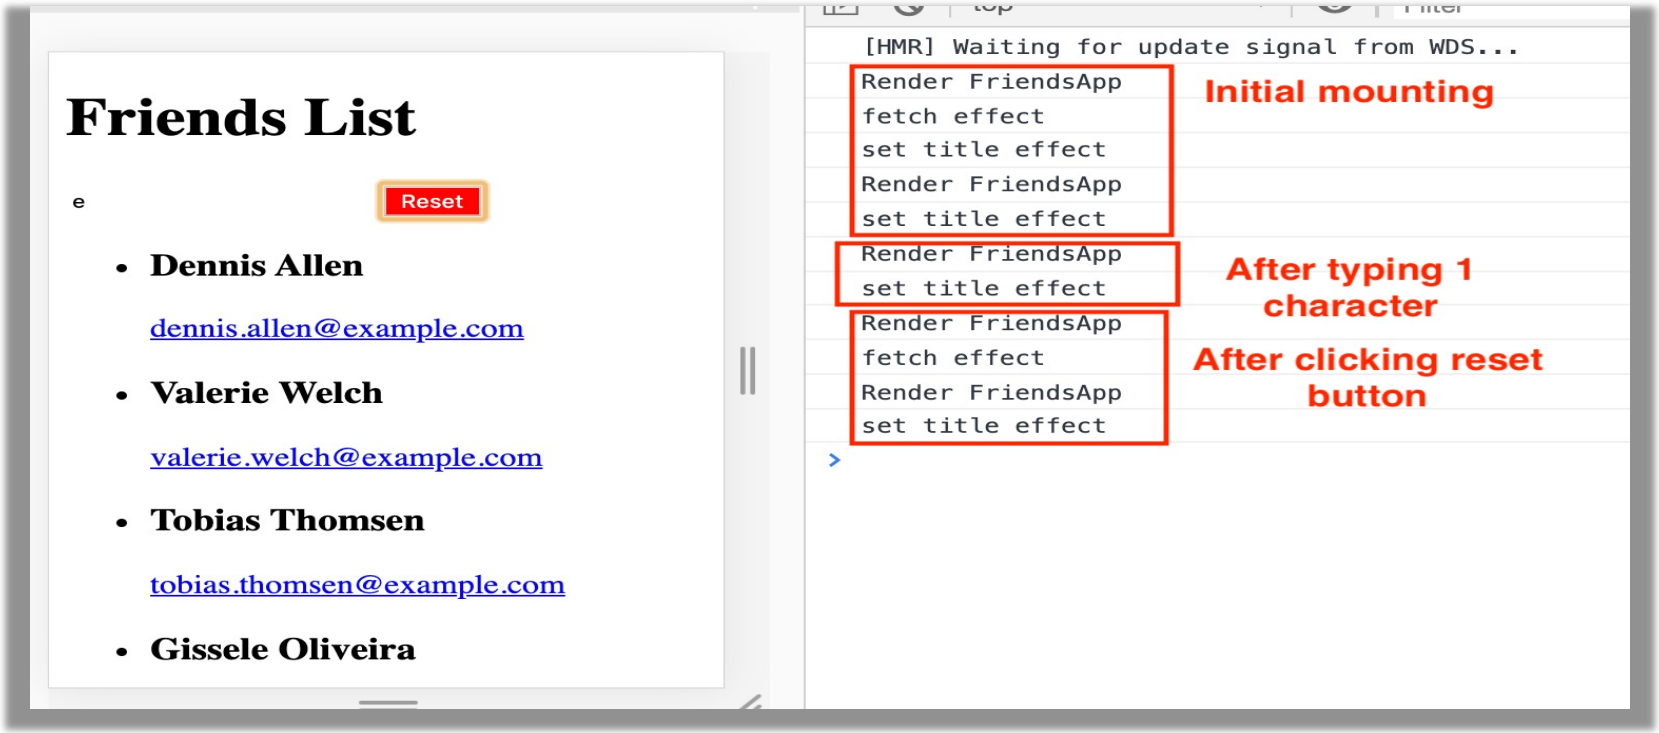
Sample App 1 (v2) - Design



- **3 state variables:**
  1. **List of friends from API.**
  2. **Text box content.**
  3. *Reset button toggle.*

- **2 side effects:**
  1. **'Fetch API data' - dependent on change to** reset button **toggle.**
  2. **'Set browser tab title' - dependent on change to matching list length.**

Sample App 1 (v2) - Events



Sample App 1 - Events.

- **On mounting of** FriensApp **component:**
  Both effects execute (Set browser tab to ’0 matches’).
  → **‘Fetch data’ effect changes ‘friends list’ state.**
  → **Component re-renders + ‘Set browser tab’ effect executes.**
- **On typing a character in the text box:**
  ‘Text box’ state change.
  → FriendsApp **rerenders + Matching friends list length changes**
  → **‘Set browser title’ effect executes.**
- **On clicking Reset button:**
  ‘Reset toggle’ state changes.
  → FriendsApp **re-renders.**
  → **‘Fetch data’ effect executes.**
  → **‘Friends list’ state changes.**
  → **FriendsApp re-renders + Matching list length changes.**
  → **‘Set browser title’ effect executes.**

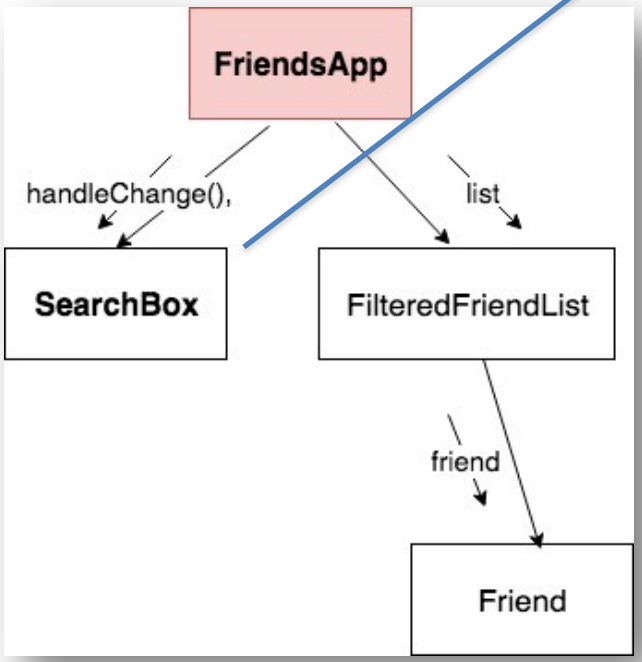
Topics

- **Hooks and Component Lifecycle.**
- **Data Flow patterns – Data Down, Action Up pattern.**
- **The Virtual DOM**

Sample App 2

(Data down, actions up pattern or Inverse data flow pattern)

- **What if a component's** state **is influenced by an** event **in a subordinate component?**
- **Solution: The** data down, action up pattern.



Data down, Action up.

Pattern:

1. Stateful **component** (FriendsApp) **provides a callback to the subordinate** (SearchBox)**.**
2. Subordinate **invokes callback when the event** (onChange) **occurs.**

```
const FriendsApp = () => {
  const [searchText, setSearchText] = useState("");
  const [friends, setFriends] = useState([]);

  useEffect(() => {…
  }, []);

  const filterChange = text =>
    setSearchText(text.toLowerCase());

  const updatedList = friends.filter(friend => {…
  });
  return (
    <>
      <h1>Friends List</h1>
      <SearchBox handleChange={filterChange } />
      <FilteredFriendList list={updatedList} />
    </>
```

```
const SearchBox = props => {
  const onChange = event => {
    event.preventDefault();
    const newText = event.target.value.toLowerCase();
    props.handleChange(newText);
  };

  return <input type="text" placeholder="Search"
           onChange={onChange} />;
};
```

Topics

- **Hooks and Component Lifecycle.**
- **Data Flow patterns – Data Down, Action Up pattern.**
- **The Virtual DOM**

Modifying the DOM

- **DOM – an internal data structure representing the browser's current 'display area' ; DOM always** in sync **with the display.**

- **Traditional performance best practice:**
  1. **Minimize direct accessing of the DOM.**
  2. **Avoid 'expensive' DOM operations.**
  3. **Update elements offline, then replace in the DOM.**
  4. **Avoid changing layouts in Javascript.**
  5. **. . . etc.**

- **Should the developer be responsible for low-level DOM optimization? Probably not.**
  - **React provides a *Virtual DOM* to shield developers from these concerns.**

The Virtual DOM

- **How React works:**
  1. **It create a lightweight, efficient form of the DOM, termed the *Virtual DOM*.**
  2. **Your app changes the V. DOM via components' JSX.**
  3. **React engine:**
     1. **Performs a *diff* operation between current and previous V. DOM instance.**
     2. **Computes the *set of changes* to apply to real DOM.**
     3. **Batch update the real DOM.**

- **Benefits:**
  a) **Cleaner, more descriptive programming model.**
  b) **Optimized DOM updates and reflows.**

Automatic Re-rendering (detail)

- **EX.: The Counter component.**

User clicks button

→ *onClick event handler executed*

→ *component state is changed*

→ *component re-executed (re-renders)*

→ *The Virtual DOM has changed*

→ *React diffs the changes between the current and previous Virtual DOM*

→ *React batch updates the Real DOM*

Re-rendering & the real DOM

- **What happens when the user types in the text box?**

User types a character in text box

→ *onChange* ***event handler executes***

→ ***Handler changes a state variable***

→ ***React re-renders*** *FriendsApp component*

→ ***React re-renders children (****FilteredFriendList****) with new prop values.***

→ ***React re-renders children of*** *FilteredFriendList****.***

(Re-rendering completed)

→ ***(Pre-commit phase) React computes the updates required to the browser's DOM***

→ ***(Commit phase) React batch updates the DOM.***

→ ***Browser repaints screen***

Summary

- **A state variable change always causes a component to re-render.**
  - **State change logic is usually part of an event handler function.**
  - **Event hadler may be in a subordinate component.**

- **Side effects:**
  - **Always execute at mount time.**
  - **The dependency array will either reference a state variable, a value computed from a state variable, or a prop.**
    - **Can be multiple entries**
  - **Callback performs the side-effect, and may also cause a state change.**

- **Data flows downward, actions flow upward.**
